Abstract

Aim of this research is the use of sonoelastography liver and spleen in dynamic monitoring of patients with diffuse liver disease. In the research – 217 patients: human male – 125 (57,6 %), females – 92 (42,4 %) ($p \geq 0,05$). It was determined by the need to use elastography over 12 months. It was identified therapeutic value of $\Delta F/\Delta L$ in dynamic observation: at odds of more than 1, it means about favorable disease course. If the value of $\Delta F/\Delta L$ in dynamic observation of less than 1, so it can be seen as a predictor of cirrhosis and possible adverse clinical outcome.

Key words: Elastography, Liver, Spleen, Cirrhosis.
