Department of Diagnostic Radiology and Mammology

Abstract

A clinical case of late diagnosis of lobular breast cancer, manifest bone metastases. Of particular interest is a complex radial diagnostics. In a clinical breast examination detected left breast skin lesions. On mammograms visualized education isodens, which had no signs of malignancy, and thickening of the skin of the areola. Given the discrepancy between clinical-ray data computed tomography breast with intravenous contrast was performed and revealed the formation of 6×8 mm, intensively accumulates contrast agent. Following the sectoral resection was verified infiltrative lobular carcinoma.

Key words: Infiltrative Lobular Breast Cancer, Primary Disseminated Breast Cancer, X-Ray Mammography, Computer Tomography, Clinical Examination of the Breast.
